LINE COUNT:	4754

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB The invention provides compositions and methods for the **synergistic** degradation of oligosaccharides by endoglucanases. The invention further provides recombinant host cells containing one or more genes encoding endoglucanses which are capable of the **synergistic** degradation of oligosaccharides. Preferred host cells of the invention are ethanologenic and capable of carrying out simultaneous saccharification and fermentation resulting in the production of ethanol from complex cellulose substrates

L4 ANSWER 2 OF 4 USPATFULL on STN

ACCESSION NUMBER:	2000:57569 USPATFULL
TITLE:	Extracellular expression of cellulose binding domains (CBD) using Bacillus

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

AB The present invention relates to Bacillus hosts transformed with a vector comprising a DNA sequence encoding for a cellulose binding domain (CBD) and capable of expressing said sequence, the expressed polypeptide protein consisting essentially of one or more non-catalytic domains; the cellulose binding domain having a molecular weight in the range of from 4 kD to 35 kD and being obtainable from a microorganism or from a plant, preferably from a bacterium or a fungus; the Bacillus host e.g. being one of the species Bacillus subtilis, Bacillus licheniformis, Bacillus megaterium, Bacillus stearothermophilos, and Bacillus amyloliquefaciens; and a Bacillus expression vector carrying an inserted DNA sequence encoding for a cellulose binding domain; and a method for producing a cellulose binding domain polypeptide in a Bacillus host cell.

AB **Erwinia** chrysanthemi produces a battery of hydrolases and lyases which are very effective in the maceration of plant cell walls. Although two endoglucanases (**CelZ** and **CelY**; formerly **EGZ** and **EGY**) are produced, **CelZ** represents approximately 95% of the total carboxymethyl cellulase activity. In this study, we have examined the effectiveness of **CelY** and **CelZ** alone and of combinations of both enzymes using carboxymethyl cellulose (CMC) and amorphous cellulose (acid-swollen cellulose) as substrates. **Synergy** was observed with both substrates. Maximal **synergy** (1.8-fold) was observed for combinations containing primarily **CelZ**; the ratio of enzyme activities produced was similar to those produced by cultures of E. chrysanthemi. **CelY** and **CelZ** were quite different in substrate preference. **CelY** was unable to hydrolyze soluble cellooligosaccharides (cellotetraose and cellopentaose) but hydrolyzed CMC to fragments averaging 10.7 glucosyl units. In contrast, **CelZ** readily hydrolyzed cellotetraose, cellopentaose, and amorphous cellulose to produce cellobiose and cellotriose as dominant products. **CelZ** hydrolyzed CMC to fragments averaging 3.6 glucosyl units. In combination, **CelZ** and **CelY** hydrolyzed CMC to products averaging 2.3 glucosyl units. **Synergy** did not require the simultaneous presence of both enzymes. Enzymatic modification of the substrate by **CelY** increased the rate and extent of hydrolysis by **CelZ** . Full **synergy** was retained by the sequential hydrolysis of CMC, provided **CelY** was used as the first enzyme. A general mechanism is proposed to explain the **synergy** between these two enzymes based primarily on differences in substrate preference.
